

Great. If your ambition is to build a **\$10B+ company** that YC would fund and that can genuinely compete with or surpass Glean, then I would stop thinking in terms of **modules** and start thinking in terms of **platform evolution**.

From this point onward, every feature should answer one question:

"Is this something Glean, Microsoft Copilot, or Notion AI could easily copy in a year?"

If the answer is **yes**, don't make it your core differentiator.

My Recommendation

I propose we design the **entire Company Brain architecture** from today until Version 1.0, with every phase having one clear goal:

```
Phase 1
↓
Universal Enterprise Data Platform

Phase 2
↓
Enterprise Knowledge Platform

Phase 3
↓
Reasoning Platform

Phase 4
↓
Organizational Intelligence Platform

Phase 5
↓
Execution Platform

Phase 6
↓
Autonomous Company Platform

Phase 7
↓
Digital Twin Company
```

Notice that **Search is only a small part** of this journey.

What we'll design together

I suggest we spend time designing each of these areas at a **Principal Engineer + YC Founder** level:

Phase 3 — Hybrid Reasoning Engine

Not just vector search.

We'll build:

- Knowledge Graph
- Hybrid Retrieval
- GraphRAG
- Multi-hop reasoning
- Multi-agent reasoning
- Source verification
- Contradiction detection
- Confidence engine
- Explainability engine

Goal:

AI should **reason**, not just retrieve.

Phase 4 — Company Intelligence Layer

This is where Company Brain becomes different.

Instead of storing documents, it stores:

- Decisions
- Processes
- Responsibilities
- Expertise
- Dependencies
- Risks
- Company policies
- Team relationships

Example:

Instead of

John edited document

it stores

John

↓

owns Payroll

↓

works with Finance

↓

approves invoices

↓

backup = Alice

Now AI understands the company.

Phase 5 — Company Learning Engine

This doesn't exist as a mature product today.

Every interaction teaches the Brain.

Employee

↓

Corrects AI

↓

Brain learns

↓

Knowledge Graph updates

↓

Retrieval improves

↓

Agents improve

↓

Future answers improve

The company trains its own AI automatically.

Phase 6 — Workflow Discovery

One of the biggest opportunities.

Don't ask customers:

"Please configure your workflows."

Instead:

Observe

↓

Meetings

↓

Slack

↓

Jira

↓

CRM

↓

Calendar

↓

Emails

↓

Now the Brain says

"This approval step is always skipped."

or

"This process has become slower over the last three months."

That's operational intelligence.

Phase 7 — Company Digital Twin

This is the feature I would want investors to remember.

The Brain builds a live model of the organization.

It understands:

People

Projects

Customers

Products

Knowledge

Processes

Dependencies

Decisions

Goals

Risks

Then you can ask:

"If we delay Product X by two weeks, what happens?"

The Brain simulates:

Engineering

↓

Sales

Marketing

Support

Revenue

Customer Impact

That moves you beyond search into decision support.

Phase 8 — Autonomous Company

Now AI doesn't only answer questions.

It can:

Observe

Plan

Ask for approval

Execute

Monitor

Learn

Examples:

Sales Agent

updates CRM

creates proposal

schedules meeting

alerts finance

asks manager for approval

This is a coordinated system of agents working from the same Company Brain.

The One Feature I Think Could Make Company Brain Category-Defining

If I had to bet on **one capability** that could become your signature, it would be this:

Organizational Memory + Decision Intelligence

Today's systems remember documents.

Your system should remember **how the company thinks**.

Imagine every important meeting becoming structured knowledge like this:

Meeting

Decision

- └ Problem
- └ Options considered
- └ Decision made
- └ Why it was chosen
- └ Risks accepted
- └ Owner
- └ Deadline
- └ Expected outcome

Six months later, someone asks:

"Why did we choose AWS instead of Azure?"

Instead of searching meeting transcripts, the Brain answers:

- The decision that was made.
- The alternatives considered.
- The reasoning behind the choice.
- Who approved it.
- Whether the expected outcome was achieved.
- Whether the decision should be revisited based on new evidence.

That is a fundamentally different product from enterprise search.

How We Should Proceed

I recommend we treat this as a serious startup architecture project, not just a coding exercise.

We'll design each remaining phase like an engineering organization at a top infrastructure company would:

1. **Business problem** — Why this capability matters.
2. **Competitive analysis** — What Glean, Microsoft Copilot, Hebbia, and others do today.
3. **Our innovation** — What Company Brain will do differently.
4. **System architecture** — Components, services, and data flow.
5. **Database schema** — Production-ready tables and relationships.
6. **API design** — Service contracts and interfaces.
7. **Scaling strategy** — Millions of documents, thousands of tenants.
8. **Security** — Enterprise-grade isolation, auditing, and governance.
9. **Implementation roadmap** — What to build first and what can wait.
10. **Investor narrative** — How to explain why this creates a defensible business.

By the end, you'll have not just a product, but a **technical architecture, product roadmap, and company narrative** that can support conversations with YC, enterprise customers,

and investors.
